

Weierstraß*

Volker Runde

Each university and each department, I guess, develops a peculiar kind of folklore: anecdotes about those of its graduates (or dropouts) that somehow managed to become famous (or notorious). Very often, there is an element of glee to these stories: “Well, he may now be a government minister, but *I* flunked him in calculus!” And also very often, it is impossible to tell truth from legend.

When I was a math student at Münster, Germany, in the 1980s, such anecdotes centered mainly around two people: Gerd Faltings, the first and only German to win the Fields medal, mathematics’ equivalent of the Nobel prize, and Karl Weierstraß¹, the man who (besides many other mathematical accomplishments) introduced ϵ s and δ s into calculus. Weierstraß had been a student at Münster in the 1830s and 1840s. There was no one around anymore who knew anybody who had known anybody who had known anybody who had known Weierstraß. But this didn’t prevent the folklore from blooming. According to folklore, Weierstraß flunked out of law school (because he spent most of his time there drinking beer and doing mathematics); then he worked for more than ten years as a school teacher in remote parts of Prussia, teaching not only mathematics, but also subjects like botany, calligraphy, and physical education. Finally, almost 40 years old, he became a famous mathematician over night, and eventually he was appointed as professor at Berlin — without ever having received a PhD.

This may sound wild, and in some points it simplifies the facts, but it is not far from the truth.

Karl Theodor Wilhelm Weierstraß was born October 31, 1815, in the village of Ostenfelde in what was then the Prussian province of Westphalia. A street and an elementary school in Ostenfelde are named after him, and his birth house — still occupied today — is listed in a local tourist guide. His father, who worked for for Prussia’s customs and taxation authorities, was sent from one post to the next within short periods of time. For the first fourteen years of Karl Weierstraß’ life, the family was more or less constantly on the move. In 1829, the father obtained an assistant’s position at the tax office in the city of Paderborn (also in Westphalia), and the family could finally settle down. Young

*The last letter is not a β , but an “ß”, a letter unique to the German alphabet, which is pronounced like an “s”.

¹Books written in English usually spell the name “Weierstrass”.

Karl enrolled at the local Catholic *Gymnasium* in Paderborn, where he excelled not only in mathematics, but also in German, Latin, and Greek. Not only was he an academically strong student — he was also quite capable of putting his brains to work on much more practical matters: At age 15, he contributed to his family’s income by doing the bookkeeping for a wealthy merchant’s widow.

Throughout his life, Weierstraß senior suffered from the fact that he did not have the right education to rise to a rank in the Prussian civil service that would have really suited his abilities. He had to content himself with relatively low level positions, not very challenging and not very well paid. Like many a father in this situation, he was determined to prevent such a fate for his bright, eldest son. When Karl graduated in 1834, his father decided to send him to Bonn to study *Kameralistik*, i.e. a combination of law, finance, and administration. Being a dutiful son, Karl went ...

... and did all he could to screw up the life his father had planned for him. He joined a *schlagende Verbindung*, a particular kind of student fraternity typical of German universities in the nineteenth century. Besides keeping the brewing industry busy, students in such a fraternity engaged in a peculiar ritual: the *Mensur*, a swordfight with a particular twist. Unlike in today’s athletic competitions, the students fought with sharp sabers. They wore protective gear which covered most of their bodies — except the cheeks. During a *Mensur*, the opponents tried to inflict gashes on one another’s cheeks. The scars resulting from these gashes were borne with pride as signs of honor and manhood². Almost two meters tall, quick on his feet, and with strong arms, Karl Weierstraß was a fearsome swordsman. His face remained unscarred, and after a while nobody was keen on challenging him anymore. Having escaped from under his father’s tutelage, he spent his years at Bonn drinking beer and wielding the saber — and seriously studying mathematics. Although he was not enrolled in mathematics, he read some of the most advanced math books of his time. When it was time for him, in 1838, to take his exams, he simply dropped out.

His family was desperate. They had made considerable financial sacrifices to secure a better future for Karl, who had let them down. Having wasted four years of his life, he needed a breadwinning degree — and that fast. So, in 1839, he enrolled at the *Akademie*, a forerunner of today’s university, in Münster to become a secondary school teacher. Although this was not really a university, but rather a teacher training college, they had one good mathematician teaching there: Christoph Gudermann. He is said to have been an abysmal teacher: Very often, he had just one student sitting in his class — Karl Weierstraß. In 1840, Weierstraß graduated. His thesis was so good that Gudermann believed it to be strong enough for a doctoral degree. However, the *Akademie* was not *really* a university: It did not have the right to grant doctorates. So, instead of receiving a

²If you find such ideas of honor and manhood absolutely revolting, you’re absolutely right.

doctorate and starting an academic career, Weierstraß left the *Akademie* as a mere school teacher.

His first job (probationary) was in Münster. One year later, he was sent to Deutsch Krona³ in the province of West Prussia as an auxiliary teacher and in 1848 to Braunsberg⁴ in East Prussia. Of course, he taught mathematics, but also physics, geography, history, German, and — believe it or not — calligraphy and physical education. Besides the demands of working full time as a teacher and having a social life — remember: he liked beer —, he found time to do research in mathematics. During his time in Braunsberg, he published a few papers in his school's yearbook. High school year books are not exactly the place where people are looking for cutting edge research in mathematics, and so, nobody noticed them. Then, in 1854, he published a paper entitled “Zur Theorie der Abelschen Functionen” in a widely respected journal. I won't even make an attempt to explain what it was about. But unlike his previous work, this one *was* noticed.

It dawned to mathematicians all over Europe that the man who was probably the leading analyst of his day was rotting in a small East Prussian town, spending most of his time teaching youngsters calligraphy and physical education. On March 31, 1854, Weierstraß finally received a doctorate: an honorary one from the university of Königsberg⁵, but nevertheless. In 1856, he accepted a position at the *Gewerbeinstitut*, an engineering school, and a year later he joined the faculty of the university of Berlin as an adjunct professor. As a teacher, he attracted large audiences. Often, he taught in front of more than 200 students. Finally, in 1860, when he was almost 50 years old, Weierstraß was appointed full professor at the university of Berlin. In the years 1873 and 1874, he was *Rektor magnificus* of the university; in 1875, he became a knight of the order “Pour le Mérite” in the category of arts and sciences, the highest honor newly unified Germany could bestow upon one of her citizens; and in 1885, on the occasion of his 70th birthday, a commemorative coin was issued.

The years of leading a double life as a secondary school teacher and a mathematical researcher had taken their toll on Weierstraß' health. A less vigorous man would probably have collapsed under the double burden after a short time only. From 1850 on, he began to suffer from attacks of dizziness which culminated in a collapse in 1861. He had to pause for a year before he could teach again, and he never recovered fully. In 1890, — at age 75! — he retired from teaching because of his failing health. The last years of his life, he spent in a wheelchair. In 1897, he died.

Weierstraß published few papers — he was very critical towards his own work. But although, he was a brilliant researcher, the greatest impact he had on mathematics was as a teacher. At Berlin he repeatedly taught a two-year course on analysis — the ancestor of all

modern introductions to calculus and analysis. Although he never wrote a textbook, notes taken in class by his students have survived and convey an impression of his lectures. The perhaps longest lasting legacy of these lectures is their emphasis on rigor. When calculus was created in the 17th century, mathematicians did not worry about rigorously proving their results. For example, the first derivative dy/dx of a function $y = f(x)$ was thought of as a quotient of two “infinitesimal”, i.e. infinitely small, quantities dy and dx . Nobody could really tell what infinitely small quantities were supposed to be, but mathematicians back then didn’t really care. The new mathematics enabled them to solve problems in physics and engineering which had been beyond the reach of human mind before. So why bother with rigor? In the 18th century, mathematicians went so far as to proclaim that rigor was for philosophers and theologians — not for mathematicians. But with the lack of rigor, contradictory results cropped up with disturbing frequency, i.e. people arrived at formulae that were obviously wrong. And if a particular formulae determines whether or not a bridge collapses, you don’t want it to be wrong. Weierstraß realized that, if calculus was to rest on solid foundations, its central notion, that of limit, had to be made rigorous. He introduced the definition which (essentially) is still used today in classes:

A number y_0 is the limit of a function $f(x)$ as x tends to x_0 if, for each $\epsilon > 0$, there is $\delta > 0$ such that $|f(x) - y_0| < \epsilon$ for each x with $|x - x_0| < \delta$.

Students may curse it, but it will not go away.

Weierstraß was not only an influential lecturer, but also one of the most prolific advisors of PhD theses of all time. There is a database on the internet⁶ which lists 31 PhD students of Weierstraß and 1346 descendants, i.e. PhDs of PhDs of PhDs of etc. of Weierstraß. Interestingly, the two of his former students who generated the most folklore weren’t his students in a technical sense.

Sofya Kovalevskaya was a young Russian noble woman who had come to Germany to study mathematics. This alone was not a small feat at a time when the very idea of a woman receiving a university education was revolutionary. For two years, she studied at Heidelberg, where authorities would not let her enroll officially, but eventually allowed her to attend lectures unofficially (provided the instructor did not object). Then she moved to Berlin to work with Weierstraß — only to find that there she was not even allowed to sit in lectures. This prompted Weierstraß, by all we know a politically conservative man, to tutor her privately. Since Kovalevskaya could not receive a doctorate from Berlin, Weierstraß used his influence to persuade the university of Göttingen to award her the degree in 1874. The following nine years, she spent jobhunting. Being a woman didn’t help. The best job she could get was teaching arithmetic at an elementary school. Finally, in 1883, she was offered a professorship at Stockholm, where she worked until her death

⁶The Mathematics Genealogy Project at <http://hcoonce.math.mankato.msus.edu/>.

in 1891 at the age of 41. Weierstraß and Kovalevskaya stayed in touch throughout her mathematical career. After her death, Weierstraß destroyed their correspondence. This fact, along with Kovalevskaya's striking beauty, gave rise to innuendo that she may have been more to Weierstraß, who never married, than just a student. May have been — but we don't know. This kind of “folklore” probably tells more about those who spread it than about those it is supposedly about.

Gösta Mittag-Leffler also was not strictly speaking Weierstraß' student. Already being enrolled at the university of Uppsala, Sweden, he came to Berlin in 1875 to attend Weierstraß' lectures, which turned out to have an enormous impact on his mathematical development. He then returned to his native Sweden, where he received his doctorate. Over the years, he became the undisputedly most influential mathematician of his time in Sweden. He made use of his clout to overcome the obstacles faced by Sofya Kovalevskaya in connection with her appointment at Stockholm. What Mittag-Leffler is most famous for, however, is not a mathematical accomplishment, but a piece of mathematical folklore. To this day, mathematicians suffer quietly from the lack of a Nobel prize in mathematics, and some say, Mittag-Leffler is to blame: According to legend, the first version of Nobel's will mentioned a prize in mathematics. Then, Nobel found out that his wife had an affair with Mittag-Leffler. Infuriated by the prospect that his wife's lover could well be the first prize winner, Nobel changed his will and removed the math prize. That's a fine piece of juicy folklore — but nothing more: Like Weierstraß, Nobel was a lifelong bachelor.
